Physiotherapy interventions evidence table – Exercise-based interventions

The following table provides a summary of level I or II evidence (according to the NHMRC evidence hierarchy) for physiotherapy-relevant interventions in RA published between January 2012 and June 2019. Interpreting the evidence can be complex. RAP-eL users should consider the following:

- There are no current studies investigating the effects of exercise programmes on early versus late rheumatoid arthritis.
- Further research is needed into the optimal content, format (individual vs. group; supervised vs. unsupervised; home vs. gym based), duration and frequency of exercise programmes.
- Further research is required to look at improving long term adherence to home exercise programmes.
- Improved reporting of adverse events is also needed in future studies. Given the systemic nature of RA and extra-articular consequences of RA (refer to Module 4) practitioners are advised to monitor articular and non-articular effects of exercise and refer to a medical practitioner where unexplained changes in exercise tolerance are observed. Any adverse effects and/or concerns regarding their cardiovascular status should be referred immediately to their medical team.
- It is important to note that many of the interventions studied are done so in isolation, so the evidence refers to the effect of the single intervention, and not the effect of a multimodal intervention.

- In the CSR, no studies were available testing a specific balance exercise programme in patients with RA. A combination of strengthening, endurance and dynamic/functional exercises were used in all studies analysed.
- A more recent RCT by da Silva showed that a 16-week neuromotor exercise programme had a statistically positive effect in neuromotor
- There is some limited evidence to support the use of specific balance or proprioceptive exercise in patients with RA
- The effects of lower limb muscle weakness on falls risk in patients with RA is unclear
- Patients with RA are at risk of falls and the associated co-morbidities of a fall
- Until further research is available, clinicians need to assess on a case by case basis whether to include balance/

sensorimotor training in patients with rheumatoid arthritis: a randomized controlled trial [link].

## Aerobic exercise

<table>
<thead>
<tr>
<th>Study</th>

<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hurkmans et al (2009) Dynamic exercise programs (aerobic and/or muscle strength training) in patients with RA</td>
<td></td>
<td></td>
<td></td>
<td>✓</td>
<td>- Aerobic exercise performed a minimum x 2 weekly appears to be a safe and effective inclusion to a RA exercise programme for improving aerobic capacity. - Aerobic exercise should not be used as a single modality, but rather an adjunct to other modalities, to address pain and functional impairment related to RA. However, when prescribed alone, it may be effective in reducing fatigue (e.g. using a walking program with pedometer support) - Aerobic exercise is recommended as routine practice when combined with strengthening exercise - There are no reported safety benefits of aerobic exercise performed in water over land based aerobic exercise.</td>
</tr>

</tbody>
</table>

- There is some evidence to support hydrotherapy in the short term
- Potential benefits including reducing pain and joint tenderness, improved mood, increased grip strength and improved patient satisfaction when compared with usual or no care (Al-Qubaeissy, 2013).
- The most recent Cochrane review (Verhagen, 2015) found insufficient evidence to support hydrotherapy (or other aquatic therapies) over other interventions in improving pain and disability e.g. land exercise, relaxation, cyclosporins.
- Barker et al (2014) also found moderate improvements in pain, QOL and physical function when compared to

- Although some studies show hydrotherapy may improve pain, joint tenderness, mood, grip strength and patient satisfaction as well as reduce disability in patients with RA in the short term, the most recent Cochrane Review reports this evidence is inconclusive.
- Evidence supporting longer term benefits is also inconclusive.
- Based on current evidence deciding between land and aquatic-based exercise should be made based on patient preference, functional capacity, safety and access to facilities.
### Tai Chi

<table>

</tr>
</tbody>
</table>

- Han et al. 2004 (3) Tai Chi for treating RA
  
- **Ekelman et al (2014)** found insufficient evidence to support of Tai Chi delivered by OT’s for RA.
- Tai Chi-based programmes had no statistically significant effect on disease activity, activities of daily living, tender and swollen joints and patient global overall rating.
- Tai Chi is suggested not to exacerbate symptoms (**Han et al., 2004**) and has statistically significant benefits in improving ankle plantarflexion.

---

### Yoga

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

- Ward et al. Complement Ther Med 2014; 22(5); 909-919.
  
- Reviews found only one study of poor quality investigating yoga for RA (the remaining studies reviewed were for other MSK conditions e.g. LBP).
- There was poor detail regarding the frequency, class setting, yoga dosage and the control group was unspecified in the RA study.
- Although improvements in

---

pain after a 40 week yoga programme were cited, methodological quality was poor resulting in a lower level of evidence. - Some patients may find yoga to be more enjoyable than other forms of land-based exercise and therefore yoga may be an appropriate selection for some patients, depending on their physical function.

- Submaximal exercise (e.g. on an exercise bike) performed by people with RA can have similar effects on endogenous pain modulation to healthy controls and hence may be beneficial as a management strategy for pain in RA (in addition to improvements in cardiovascular fitness and strength)

- Both exercise types were more effective than a control (drug therapy) in improving:
  - Function
  - QOL, and
  - Muscle strength

- Consider recommending gym based exercise (strengthening and cardiovascular) particularly to patients < 40yrs (better compliance)
- Supervised or gym based exercise will improve function,
- Compliance with supervised exercise at 6 months is better than that of unsupervised gym-based exercise (except for patients <40yrs with early RA).
- Poor detail given in the study about the content of the specific exercise interventions.

### Upper extremity functional exercise training in combination with self-management education

<table>
<thead>
<tr>
<th></th>
<th>RCT</th>
<th>SR</th>
<th>MA</th>
<th>CSR</th>
</tr>
</thead>
</table>

- Manning et al (2014) investigated upper extremity functional exercise training integrated with self-management education delivered in a group format (compared to HEP alone).
- They found significant improvements in upper limb function (DASH outcome measure) at 12 but not 36 weeks.
- Improvements were also seen in hand function, grip strength, self-efficacy, joint count and pain.
- Benefits were maintained at 36 weeks for pain and self-efficacy.

### Specific hand exercise

<table>
<thead>
<tr>
<th></th>
<th>RCT</th>
<th>SR</th>
<th>MA</th>
<th>CSR</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>✓</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- A specific hand exercise programme in addition to

- Including functional upper limb exercise (and education) to a HEP improves upper limb function and strength.
- Improvements in pain and self-efficacy may be longer lasting than improvements in upper limb strength and function.
- Refer to the study Manning et al (2014) for further detail about the content and delivery of self-management education and specific exercise examples.

- Moderate intensity patient-specific hand strengthening

usual care produced significant but small (4.3 points) difference measured with the Michigan Hand Questionnaire
• No significant differences were seen in pain, medication or healthcare use between the groups (Lamb et al, 2015)
• Twice weekly physiotherapy-guided hand strengthening exercise sessions (total 20 sessions) in addition to 3 x weekly home exercises resulted in significant improvements in grip strength, pinch strength and hand function.

• Numbers of treatment sessions ranged from 6-20 (Physiotherapy/OT) to progress the resistance and repetitions of these exercises.
• See Cima et al (2013) for details of strengthening exercises including pictures of exercises given.
• At 2 yr follow-up (Williamson et al 2017), there was no difference between the intervention and control groups, although the exercise participants were significantly improved compared with baseline. The reduction in hand function at 2yrs, compared with previously time points coincided with a reduction in exercise adherence, suggesting that long-term adherence is needed to maintain function.

Flexibility exercises
• No effect on passive or active
- Flexibility exercises do not

<table>
<thead>
<tr>
<th>(ROM and stretching exercises)</th>
<th>RCT</th>
<th>SR</th>
<th>MA</th>
<th>CSR</th>
</tr>
</thead>
<tbody>
<tr>
<td>Rausch Osthoff AK et al. Effects of exercise and physical activity promotion: meta-analysis informing the 2018 EULAR recommendations for physical activity in people with rheumatoid arthritis, spondyloarthritis and hip/knee osteoarthritis. [link]</td>

<td></td>
<td>✓</td>
<td></td>
</tr>
</tbody>
</table>

ROM was demonstrated in a meta-analysis of flexibility exercises (ROM, stretching exercises) combined with aerobic or strengthening exercises, compared with no exercise or usual care. appear to be effective in patients with RA. Considering potential for joint instability, this mode of exercise may be unsuitable for some patients with RA.
